

MATRIX MATH TRANSPOSE

THE MATRIX MATH TRANSPOSE: A DEEP DIVE INTO SWAPPING ROWS AND COLUMNS

MATRIX MATH TRANSPOSE IS A FUNDAMENTAL OPERATION IN LINEAR ALGEBRA, A CONCEPT THAT UNLOCKS A VAST ARRAY OF POSSIBILITIES IN FIELDS RANGING FROM COMPUTER GRAPHICS AND DATA SCIENCE TO PHYSICS AND ENGINEERING. ESSENTIALLY, TRANSPOSING A MATRIX INVOLVES A SIMPLE YET POWERFUL TRANSFORMATION: SWAPPING ITS ROWS AND COLUMNS. THIS OPERATION, WHILE SEEMINGLY STRAIGHTFORWARD, HAS PROFOUND IMPLICATIONS AND APPLICATIONS. UNDERSTANDING THE MATRIX TRANSPOSE IS CRUCIAL FOR ANYONE WORKING WITH SYSTEMS OF EQUATIONS, PERFORMING TRANSFORMATIONS, OR ANALYZING LARGE DATASETS. THIS ARTICLE WILL EXPLORE THE DEFINITION, PROPERTIES, CALCULATION METHODS, AND NUMEROUS APPLICATIONS OF THE MATRIX TRANSPOSE, PROVIDING A COMPREHENSIVE GUIDE TO THIS ESSENTIAL MATHEMATICAL TOOL. WE'LL BREAK DOWN HOW IT WORKS, WHY IT'S USEFUL, AND WHERE YOU'LL MOST LIKELY ENCOUNTER IT.

PROPERTIES OF THE MATRIX TRANSPOSE

APPLICATIONS OF THE MATRIX TRANSPOSE

FREQUENTLY ASKED QUESTIONS ABOUT MATRIX MATH TRANSPOSE

UNDERSTANDING THE MATRIX TRANSPOSE

AT ITS CORE, THE TRANSPOSE OF A MATRIX IS A NEW MATRIX DERIVED FROM THE ORIGINAL BY SWITCHING ITS ROWS AND COLUMNS. IF WE HAVE A MATRIX DENOTED AS ' A ', ITS TRANSPOSE IS TYPICALLY REPRESENTED AS ' A^T ' OR ' A ' WITH A SUPERSCRIPT ' T '. THIS TRANSFORMATION MEANS THAT THE ELEMENT LOCATED IN THE i -TH ROW AND j -TH COLUMN OF THE ORIGINAL MATRIX ' A ' WILL BE FOUND IN THE j -TH ROW AND i -TH COLUMN OF ITS TRANSPOSE, ' A^T '. THIS SIMPLE ACT OF REFLECTION ACROSS THE MAIN DIAGONAL, WHERE ELEMENTS ARE SWAPPED, IS THE ESSENCE OF MATRIX TRANSPOSITION.

THINK OF IT LIKE THIS: IF YOU HAVE A TABLE OF DATA WHERE ROWS REPRESENT DIFFERENT PEOPLE AND COLUMNS REPRESENT THEIR VARIOUS ATTRIBUTES (HEIGHT, WEIGHT, AGE), TRANSPOSING IT WOULD MEAN THAT EACH ROW WOULD NOW REPRESENT AN ATTRIBUTE, AND EACH COLUMN WOULD REPRESENT A PERSON. THE INFORMATION IS THE SAME, JUST REORGANIZED. THIS REORGANIZATION IS WHAT MAKES THE TRANSPOSE SO VERSATILE. IT'S NOT JUST ABOUT REARRANGING NUMBERS; IT'S ABOUT CHANGING THE PERSPECTIVE FROM WHICH YOU VIEW THE DATA OR THE TRANSFORMATION REPRESENTED BY THE MATRIX.

DEFINITION AND NOTATION

FORMALLY, LET ' A ' BE AN $m \times n$ MATRIX, MEANING IT HAS ' m ' ROWS AND ' n ' COLUMNS. THE ELEMENT IN THE i -TH ROW AND j -TH COLUMN OF ' A ' IS DENOTED AS A_{ij} . THE TRANSPOSE OF ' A ', DENOTED AS ' A^T ', IS AN $n \times m$ MATRIX WHERE THE ELEMENT IN THE j -TH ROW AND i -TH COLUMN IS GIVEN BY $A^T_{ji} = A_{ij}$. THE DIMENSIONS OF THE TRANSPOSED MATRIX ARE FLIPPED COMPARED TO THE ORIGINAL MATRIX. SO, AN $m \times n$ MATRIX BECOMES AN $n \times m$ MATRIX AFTER TRANSPOSITION. THIS IS A KEY CHARACTERISTIC TO REMEMBER.

THE NOTATION FOR THE TRANSPOSE IS QUITE STANDARD ACROSS MATHEMATICAL AND COMPUTATIONAL CONTEXTS. YOU'LL MOST COMMONLY SEE IT WRITTEN WITH A SUPERSCRIPT ' T ', AS IN ' A^T '. IN SOME TEXTS, YOU MIGHT ALSO ENCOUNTER 'A PRIME' (A') OR A TRANSPOSE SYMBOL. REGARDLESS OF THE NOTATION, THE UNDERLYING OPERATION REMAINS THE SAME: SWAPPING ROWS AND COLUMNS. IT'S A UNIVERSALLY RECOGNIZED SYMBOL THAT SIGNIFIES THIS PARTICULAR MATRIX TRANSFORMATION.

VISUALIZING THE TRANSPOSE OPERATION

IMAGINE A 2x3 MATRIX LIKE THIS:

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$$

HERE, 'A' HAS 2 ROWS AND 3 COLUMNS. TO FIND ITS TRANSPOSE, 'A^T', WE'LL SWAP THE ROWS AND COLUMNS. THE FIRST ROW OF 'A' ([1, 2, 3]) BECOMES THE FIRST COLUMN OF 'A^T'. THE SECOND ROW OF 'A' ([4, 5, 6]) BECOMES THE SECOND COLUMN OF 'A^T'. SO, 'A^T' WOULD LOOK LIKE:

$$A^T = \begin{bmatrix} 1 & 4 \\ 2 & 5 \\ 3 & 6 \end{bmatrix}$$

NOTICE HOW THE DIMENSIONS HAVE ALSO CHANGED FROM 2x3 TO 3x2. THE ELEMENT a_{12} (WHICH IS 2) IN MATRIX A IS NOW IN THE POSITION a_{21} IN MATRIX A^T. THIS SIMPLE VISUAL EXAMPLE SOLIDIFIES THE CONCEPT OF ROW-COLUMN SWAPPING.

HOW TO CALCULATE A MATRIX TRANSPOSE

CALCULATING THE TRANSPOSE OF A MATRIX IS A PROCEDURAL TASK THAT CAN BE BROKEN DOWN INTO SIMPLE STEPS. WHETHER YOU'RE DEALING WITH A SMALL 2x2 MATRIX OR A MUCH LARGER ONE, THE UNDERLYING LOGIC REMAINS CONSISTENT. IT'S A MECHANICAL PROCESS OF REORIENTING THE ELEMENTS BASED ON THEIR ORIGINAL ROW AND COLUMN INDICES.

STEP-BY-STEP CALCULATION

TO CALCULATE THE TRANSPOSE OF A MATRIX 'A', FOLLOW THESE STEPS:

- IDENTIFY THE DIMENSIONS OF THE ORIGINAL MATRIX 'A'. LET'S SAY IT'S AN M X N MATRIX.
- CREATE A NEW MATRIX, 'A^T', WITH DIMENSIONS N X M.
- FOR EACH ELEMENT a_{ij} IN MATRIX 'A' (WHERE 'i' IS THE ROW INDEX AND 'j' IS THE COLUMN INDEX), PLACE THIS ELEMENT INTO THE j-TH ROW AND i-TH COLUMN OF THE TRANSPOSED MATRIX 'A^T'.
- REPEAT THIS FOR ALL ELEMENTS IN THE ORIGINAL MATRIX.

THIS SYSTEMATIC APPROACH ENSURES THAT EVERY ELEMENT IS CORRECTLY REPOSITIONED IN THE TRANSPOSED MATRIX. IT'S A STRAIGHTFORWARD ALGORITHM THAT COMPUTERS CAN EXECUTE VERY EFFICIENTLY.

EXAMPLES OF TRANSPOSING DIFFERENT MATRIX SIZES

LET'S LOOK AT A FEW MORE EXAMPLES TO BUILD OUR CONFIDENCE.

EXAMPLE 1: A 3x3 MATRIX

CONSIDER THE MATRIX B:

$$B = \begin{bmatrix} 7 & 8 & 9 \\ 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$$

THE TRANSPOSE, B^T , WILL BE:

$$B^T = \begin{bmatrix} 7 & 1 & 4 \\ 8 & 2 & 5 \\ 9 & 3 & 6 \end{bmatrix}$$

NOTICE HOW THE MAIN DIAGONAL ELEMENTS (7, 2, 6) REMAIN IN THEIR POSITIONS RELATIVE TO THE DIAGONAL ITSELF, BUT THEIR INDICES SWAP (E.G., a_{22} BECOMES a_{22}). ELEMENTS OFF THE DIAGONAL, LIKE 8 (a_{12}) AND 1 (a_{21}), ARE SWAPPED TO THEIR NEW POSITIONS IN B^T (a_{21} AND a_{12} , RESPECTIVELY).

EXAMPLE 2: A COLUMN VECTOR

A COLUMN VECTOR CAN BE THOUGHT OF AS A MATRIX WITH ONE COLUMN. LET'S TAKE VECTOR 'v':

$$v = \begin{bmatrix} 10 \\ 20 \\ 30 \end{bmatrix}$$

THIS IS A 3×1 MATRIX. ITS TRANSPOSE, v^T , WILL BE A 1×3 MATRIX (A ROW VECTOR):

$$v^T = \begin{bmatrix} 10 & 20 & 30 \end{bmatrix}$$

THIS IS A VERY COMMON OPERATION WHEN WORKING WITH VECTORS IN MACHINE LEARNING AND OTHER DATA-INTENSIVE FIELDS.

PROPERTIES OF THE MATRIX TRANSPOSE

THE MATRIX TRANSPOSE ISN'T JUST A STANDALONE OPERATION; IT HAS SEVERAL INHERENT PROPERTIES THAT MAKE IT INCREDIBLY USEFUL IN THEORETICAL MATHEMATICS AND PRACTICAL APPLICATIONS. THESE PROPERTIES OFTEN SIMPLIFY COMPLEX CALCULATIONS AND PROVIDE INSIGHTS INTO MATRIX BEHAVIOR.

DOUBLE TRANSPOSITION

ONE OF THE MOST FUNDAMENTAL PROPERTIES IS THAT TRANSPOSING A MATRIX TWICE RETURNS THE ORIGINAL MATRIX. IN MATHEMATICAL TERMS, $(A^T)^T = A$. THIS IS INTUITIVE BECAUSE THE FIRST TRANSPOSE SWAPS ROWS AND COLUMNS, AND THE SECOND TRANSPOSE SWAPS THEM BACK, EFFECTIVELY UNDOING THE OPERATION. IT'S LIKE FOLDING A PIECE OF PAPER AND THEN UNFOLDING IT; YOU RETURN TO THE ORIGINAL STATE.

TRANSPOSE OF A SUM

THE TRANSPOSE OF THE SUM OF TWO MATRICES IS EQUAL TO THE SUM OF THEIR TRANSPOSES. IF YOU HAVE TWO MATRICES, A AND B , OF THE SAME DIMENSIONS, THEN $(A + B)^T = A^T + B^T$. THIS DISTRIBUTIVE PROPERTY IS CRUCIAL FOR SIMPLIFYING EXPRESSIONS INVOLVING MATRIX SUMS AND TRANSPOSES. IT MEANS YOU CAN PERFORM THE ADDITION FIRST AND THEN TRANSPOSE, OR TRANSPOSE EACH MATRIX INDIVIDUALLY AND THEN ADD THEM, AND YOU'LL ARRIVE AT THE SAME RESULT.

TRANSPOSE OF A PRODUCT

THIS PROPERTY IS SLIGHTLY MORE COMPLEX BUT EXTREMELY IMPORTANT: THE TRANSPOSE OF A PRODUCT OF TWO MATRICES IS EQUAL TO THE PRODUCT OF THEIR TRANSPOSES IN REVERSE ORDER. FOR MATRICES A AND B , $(AB)^T = B^T A^T$. THIS IS A KEY RULE TO REMEMBER, ESPECIALLY WHEN DEALING WITH MATRIX MULTIPLICATIONS THAT INVOLVE TRANSPOSES. IT'S A BIT LIKE REVERSING THE ORDER OF OPERATIONS WHEN UNDOING SOMETHING. IF YOU PERFORM A THEN B , TO REVERSE THE ENTIRE OPERATION USING TRANSPOSES, YOU NEED TO ADDRESS B FIRST, THEN A .

TRANSPOSE OF A SCALAR MULTIPLE

MULTIPLYING A MATRIX BY A SCALAR (A SINGLE NUMBER) AND THEN TRANSPOSING IT IS THE SAME AS TRANSPOSING THE MATRIX FIRST AND THEN MULTIPLYING BY THE SCALAR. FOR A SCALAR ' c ' AND A MATRIX ' A ', $(cA)^T = cA^T$. THIS PROPERTY IS QUITE STRAIGHTFORWARD AND SIMPLIFIES CALCULATIONS WHEN A MATRIX IS SCALED.

TRANSPOSE AND SYMMETRIC MATRICES

A SPECIAL CLASS OF MATRICES CALLED SYMMETRIC MATRICES ARE THOSE THAT ARE EQUAL TO THEIR OWN TRANSPOSE. A MATRIX ' A ' IS SYMMETRIC IF $A = A^T$. THIS MEANS THAT THE ELEMENT IN THE i -TH ROW AND j -TH COLUMN IS EQUAL TO THE ELEMENT IN THE j -TH ROW AND i -TH COLUMN ($A_{ij} = A_{ji}$) FOR ALL i AND j . THESE MATRICES ARE OFTEN ENCOUNTERED IN AREAS LIKE QUADRATIC FORMS AND STATISTICS.

TRANSPOSE AND SKEW-SYMMETRIC MATRICES

CONVERSELY, A SKEW-SYMMETRIC MATRIX IS ONE WHOSE TRANSPOSE IS ITS NEGATIVE. A MATRIX ' A ' IS SKEW-SYMMETRIC IF $A^T = -A$. THIS IMPLIES THAT THE DIAGONAL ELEMENTS MUST BE ZERO ($A_{ii} = -A_{ii}$, SO $2A_{ii} = 0$, WHICH MEANS $A_{ii} = 0$) AND OFF-DIAGONAL ELEMENTS SATISFY $A_{ij} = -A_{ji}$. THESE MATRICES APPEAR IN DIFFERENTIAL EQUATIONS AND CERTAIN AREAS OF PHYSICS.

APPLICATIONS OF THE MATRIX TRANSPOSE

THE MATRIX TRANSPOSE IS FAR FROM BEING A PURELY THEORETICAL CONCEPT; IT'S A WORKHORSE IN MANY PRACTICAL DOMAINS. ITS ABILITY TO REORIENT DATA AND SIMPLIFY CALCULATIONS MAKES IT INDISPENSABLE ACROSS VARIOUS DISCIPLINES.

LINEAR REGRESSION AND DATA ANALYSIS

IN LINEAR REGRESSION, THE GOAL IS TO FIND THE BEST-FITTING LINE (OR HYPERPLANE) THROUGH A SET OF DATA POINTS. THE SOLUTION FOR THE REGRESSION COEFFICIENTS OFTEN INVOLVES THE NORMAL EQUATION, WHICH PROMINENTLY FEATURES THE TRANSPOSE OF THE DESIGN MATRIX (A MATRIX CONTAINING THE INDEPENDENT VARIABLES). THE FORMULA FOR THE LEAST-SQUARES SOLUTION INVOLVES $(X^T X)^{-1} X^T Y$, WHERE X IS THE DESIGN MATRIX AND Y IS THE VECTOR OF DEPENDENT VARIABLES.

THE TRANSPOSE OF X IS CRITICAL HERE FOR CALCULATING THE COVARIANCE MATRIX ($X^T X$) AND PROJECTIONS.

THIS IS A PRIME EXAMPLE OF HOW MATRIX MATH TRANSPOSE IS USED TO DISTILL INFORMATION FROM DATA. BY TRANSPOSING THE DESIGN MATRIX, WE CAN EFFECTIVELY COMPUTE HOW DIFFERENT FEATURES RELATE TO EACH OTHER AND TO THE OUTCOME WE'RE TRYING TO PREDICT. THIS IS THE BEDROCK OF STATISTICAL MODELING AND MACHINE LEARNING ALGORITHMS.

COMPUTER GRAPHICS AND TRANSFORMATIONS

IN COMPUTER GRAPHICS, TRANSFORMATIONS LIKE ROTATION, SCALING, AND TRANSLATION ARE OFTEN REPRESENTED BY MATRICES. WHILE TRANSLATION CAN BE A BIT DIFFERENT, ROTATION AND SCALING MATRICES CAN BE COMBINED AND MANIPULATED USING MATRIX MULTIPLICATION AND, CONSEQUENTLY, TRANSPOSITION. FOR INSTANCE, THE INVERSE OF A ROTATION MATRIX IS SIMPLY ITS TRANSPOSE. THIS IS A MASSIVE COMPUTATIONAL SHORTCUT, AS CALCULATING A MATRIX INVERSE CAN BE COMPLEX, WHEREAS TRANSPOSING IS VERY SIMPLE.

IMAGINE ROTATING AN OBJECT IN A 3D GAME. THE MATRIX THAT DEFINES THAT ROTATION HAS A SPECIAL PROPERTY: ITS TRANSPOSE WILL PERFORM THE OPPOSITE ROTATION. THIS IS INCREDIBLY USEFUL FOR UNDOING TRANSFORMATIONS OR CALCULATING NEW ORIENTATIONS EFFICIENTLY WITHOUT COMPLEX INVERSE CALCULATIONS. IT'S LIKE HAVING A BUILT-IN UNDO BUTTON FOR CERTAIN TRANSFORMATIONS.

SOLVING SYSTEMS OF LINEAR EQUATIONS

WHILE NOT ALWAYS THE MOST DIRECT METHOD FOR SOLVING SYSTEMS OF EQUATIONS, THE CONCEPT OF THE TRANSPOSE IS CLOSELY RELATED TO CONCEPTS LIKE ORTHOGONAL VECTORS AND LEAST-SQUARES SOLUTIONS, WHICH ARE USED TO FIND APPROXIMATE SOLUTIONS WHEN EXACT SOLUTIONS DON'T EXIST. THE TRANSPOSE PLAYS A ROLE IN ALGORITHMS THAT DETERMINE THE NULL SPACE AND COLUMN SPACE OF A MATRIX, WHICH ARE FUNDAMENTAL TO UNDERSTANDING THE SOLUTION SPACE OF LINEAR SYSTEMS.

QUANTUM MECHANICS AND PHYSICS

IN QUANTUM MECHANICS, STATE VECTORS ARE OFTEN REPRESENTED AS COLUMN MATRICES. OPERATORS, WHICH REPRESENT PHYSICAL OBSERVABLES, ARE ALSO MATRICES. THE CONCEPT OF THE HERMITIAN CONJUGATE (OR ADJOINT) OF AN OPERATOR, WHICH IS CLOSELY RELATED TO THE TRANSPOSE (ESPECIALLY FOR REAL MATRICES), IS FUNDAMENTAL. THE HERMITIAN CONJUGATE IS USED TO DEFINE SELF-ADJOINT OPERATORS, WHICH CORRESPOND TO OBSERVABLE QUANTITIES IN QUANTUM MECHANICS. THIS CONNECTION HIGHLIGHTS THE DEEP THEORETICAL IMPORTANCE OF TRANSPOSITION AND ITS EXTENSIONS.

SIGNAL PROCESSING

IN SIGNAL PROCESSING, DATA IS OFTEN REPRESENTED AS VECTORS OR MATRICES. OPERATIONS LIKE FILTERING AND TRANSFORMATIONS (E.G., FOURIER TRANSFORMS) CAN BE EXPRESSED USING MATRIX ALGEBRA. THE TRANSPOSE CAN BE USED IN ALGORITHMS FOR RECONSTRUCTING SIGNALS, CALCULATING CORRELATIONS BETWEEN DIFFERENT PARTS OF A SIGNAL, OR PROCESSING MULTI-CHANNEL DATA. FOR EXAMPLE, WHEN DEALING WITH MULTIPLE SENSORS OR AUDIO TRACKS, TRANSPOSING MATRICES CAN HELP ALIGN AND COMPARE DATA STREAMS EFFECTIVELY.

FREQUENTLY ASKED QUESTIONS ABOUT MATRIX MATH TRANSPOSE

Q: WHAT IS THE MAIN DIFFERENCE BETWEEN A MATRIX AND ITS TRANSPOSE?

A: THE MAIN DIFFERENCE IS THE ORIENTATION OF ELEMENTS. IN A TRANSPOSE, THE ROWS OF THE ORIGINAL MATRIX BECOME THE COLUMNS, AND THE COLUMNS OF THE ORIGINAL MATRIX BECOME THE ROWS. THE ELEMENT AT POSITION (i, j) IN THE ORIGINAL MATRIX MOVES TO POSITION (j, i) IN THE TRANSPOSED MATRIX, AND THE DIMENSIONS OF THE MATRIX ARE SWAPPED (AN $M \times N$ MATRIX BECOMES AN $N \times M$ MATRIX).

Q: CAN ANY MATRIX BE TRANSPOSED?

A: YES, ANY MATRIX, REGARDLESS OF ITS SIZE OR WHETHER IT CONTAINS REAL OR COMPLEX NUMBERS, CAN BE TRANSPOSED. THE OPERATION OF SWAPPING ROWS AND COLUMNS IS UNIVERSALLY APPLICABLE TO ALL MATRICES.

Q: WHEN IS A MATRIX EQUAL TO ITS TRANSPOSE?

A: A MATRIX IS EQUAL TO ITS TRANSPOSE WHEN IT IS A SYMMETRIC MATRIX. THIS MEANS THAT THE ELEMENT IN THE i -TH ROW AND j -TH COLUMN IS EQUAL TO THE ELEMENT IN THE j -TH ROW AND i -TH COLUMN FOR ALL i AND j .

Q: HOW DOES THE TRANSPOSE HELP IN FINDING THE INVERSE OF A MATRIX?

A: WHILE THE TRANSPOSE ITSELF ISN'T THE INVERSE, IT PLAYS A CRUCIAL ROLE IN CERTAIN MATRIX INVERSION METHODS AND IN UNDERSTANDING MATRIX PROPERTIES RELATED TO INVERSION. FOR EXAMPLE, FOR ORTHOGONAL MATRICES, THE TRANSPOSE IS EQUAL TO THE INVERSE, OFFERING A SIGNIFICANT COMPUTATIONAL SHORTCUT. THE TRANSPOSE IS ALSO FUNDAMENTAL IN CALCULATING THE INVERSE OF THE MATRIX PRODUCT $X^T X$ IN LINEAR REGRESSION.

Q: IS THE TRANSPOSE OPERATION COMPUTATIONALLY EXPENSIVE?

A: NO, THE TRANSPOSE OPERATION IS GENERALLY VERY COMPUTATIONALLY INEXPENSIVE. IT INVOLVES REARRANGING ELEMENTS RATHER THAN PERFORMING COMPLEX ARITHMETIC OPERATIONS LIKE MULTIPLICATION OR DIVISION FOR EACH ELEMENT, MAKING IT ONE OF THE SIMPLER MATRIX OPERATIONS.

Q: WHAT IS THE DIFFERENCE BETWEEN A TRANSPOSE AND AN ADJOINT OF A MATRIX?

A: FOR REAL MATRICES, THE TRANSPOSE AND THE ADJOINT (OR CONJUGATE TRANSPOSE FOR COMPLEX MATRICES) ARE CLOSELY RELATED. THE ADJOINT IS OBTAINED BY TAKING THE TRANSPOSE AND THEN REPLACING EACH ELEMENT WITH ITS COMPLEX CONJUGATE. FOR MATRICES WITH ONLY REAL NUMBERS, THE ADJOINT IS IDENTICAL TO THE TRANSPOSE.

Q: WHY DO WE SWAP THE ORDER OF MATRICES WHEN TAKING THE TRANSPOSE OF A PRODUCT, I.E., $(AB)^T = B^T A^T$?

A: THIS PROPERTY ARISES FROM THE DEFINITION OF MATRIX MULTIPLICATION AND TRANSPOSITION. WHEN YOU MULTIPLY MATRICES A AND B , THE ELEMENT IN THE i -TH ROW AND j -TH COLUMN OF AB IS A DOT PRODUCT INVOLVING THE i -TH ROW OF A AND THE j -TH COLUMN OF B . WHEN YOU TRANSPOSE THIS PRODUCT, YOU ARE EFFECTIVELY SWAPPING THE ROLES OF ROWS AND COLUMNS. TO RECONSTRUCT THIS RESULT FROM THE TRANSPOSED MATRICES, YOU NEED TO USE THE j -TH ROW OF B^T (WHICH WAS THE j -TH COLUMN OF B) AND THE i -TH COLUMN OF A^T (WHICH WAS THE i -TH ROW OF A), LEADING TO THE $B^T A^T$ ORDER.
